**Abstract**

**Introduction:** The wounds infection remains a medical problem worldwide due to associated morbidity, mortality and economic burden. Wounds can be infected with bacteria or yeast and the source is usually hosts normal flora and/or the hospital environment. Since *Pseudomonas aeruginosa* is the most common gram-negative non fermenter opportunistic bacteria associated with nosocomial infections. The present study was undertaken to know the antibiotic susceptibility patterns of this pathogen.

**Materials and Methods:** It was a cross-sectional study carried out over a period of one year. Pus samples collected at source were processed as per standard bacteriological techniques for aerobic cultures. They were inoculated on 5% Blood agar and Mac-Conkey’s agar and incubated aerobically for 24-48 hours at 37 degree before reporting them as sterile. Anaerobic cultures were not done. Non lactose fermenting colonies on MacConkey agar were subjected to oxidase test. These oxidase positive isolates were further identified by Vitek-2 Compact (Biomerieux) using gram negative identification cards, following manufacturer’s guidelines. Antimicrobial sensitivity was also determined by same system using 281 AST cards. Antibiotic sensitivity results were interpreted as per CLSI guidelines.

**Results:** A total of 1566 wound swab/pus samples from patients with infected wounds were processed for culture and sensitivity testing from January 2018 to November 2018. The present study comprised of 101 isolates of *Pseudomonas aeruginosa*. Isolation rate was highest in the age group 20-40 years followed by those above 60 years of age. Most of the isolates obtained were multi-drug resistant. Highest sensitivity was seen in Amikacin and Imipenem.

**Conclusion:** In conclusion, *Pseudomonas aeruginosa* which is a common Gram negative bacteria isolated from wound infections and also highly resistant to different types of antibiotics could be a reason for high morbidity and mortality in hospitalised patients. Therefore a regular surveillance of antibiotic resistance of these organisms is needed to prevent indiscriminate use of antibiotics leading to emergence of drug resistance among these pathogens.

**Keywords:** Pseudomonas aeruginosa, Nosocomial infections, Multi-drug resistant.

**Introduction**

The wounds infection remains a medical problem worldwide due to associated morbidity, mortality and economic burden.¹² Wounds are generally infected with bacteria or yeast, and the source is usually hosts normal flora and/or the hospital environment.³ Since these infections are frequently polymicrobial in nature so bacteriological work up is also demanding hence usually neglected in under-resourced settings. However bacteriological investigation is mandatory to know the bacterial species causing the infection and their resistance profile to enables targeted antimicrobial therapy. Data from previous studies reveals that *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Escherichia coli* and *Acinetobacter spp.* are among the commonly isolated pathogens from infected wounds.⁴⁵ Increasing antimicrobial resistance among these bacteria is a major cause of concern worldwide. Thus antimicrobial resistance data is needed so as to guide the clinicians to formulate an empirical treatment for the patients and policy makers to update the treatment guidelines. This can contribute to prevention and control of antimicrobial drug resistance.

Since *Pseudomonas aeruginosa* is the most common gram-negative non fermenter opportunistic bacteria associated with nosocomial infections. The present study was undertaken to know the antibiotic susceptibility patterns of this pathogen.

**Materials and Methods**

**Study design**

It was a cross-sectional study from January 2018 to November 2018. Data collection included information about, age & sex of the patients and a brief clinical history of illness like if a wound was not healing well or exuding pus or fluid.

**Settings**

The study was carried out in Microbiology department, Sri Guru Ram Das Institute of Medical Science and Research, a tertiary care hospital in North India.

**Sample size**

The study comprised of a total of 101 non-repeat isolates of *Pseudomonas aeruginosa* obtained from wound swab/pus.
received in Microbiology lab for culture & sensitivity testing

Inclusion criteria
All isolates obtained from wound swab/pus which formed non lactose fermenting colonies on MacConkey agar, oxidase test positive and further confirmed as *Pseudomonas aeruginosa* by Vitek-2 Compact (Biomerieux) were included in the study.

Exclusion criteria
Species of *Pseudomonas* other than *Pseudomonas aeruginosa* were exclude from the study.

Ethical clearance for the study was obtained from the institutional ethics committee.

Methods
Pus samples were collected at source (out-patient clinic and in the wards) using sterile cotton swabs, following departmental guideline; two swabs per patient and were send to the Microbiology department for bacteriological work up. All pus samples were processed as per standard bacteriological techniques for aerobic cultures. They were inoculated on 5% Blood agar and Mac-Conkey’s agar and incubated aerobically for 24-48 hours at 37 degree before reporting them as sterile. Anaerobic cultures were not done. Non lactose fermenting colonies on MacConkey agar were subjected to oxidase test. These oxidase positive isolates were further identified by Vitek-2 Compact (Biomerieux) using gram negative identification cards, following manufacturer’s guidelines. Antimicrobial sensitivity was also determined by same system using 281 AST cards. Antibiotic sensitivity results were interpreted as per CLSI guidelines.

Statistical analysis
SPSS version 17.0 software and MS excel 2007 were used for statistic analysis. p <0.05 was considered significant.

Results
A total of 1566 wound swab/pus samples from patients with infected wounds were processed for culture and sensitivity testing from January 2018 to November 2018.

The present study comprised of 101 isolates of *Pseudomonas aeruginosa*. Of these 101 isolates, 58(57.42%) were obtained from pus samples of male patients and 43(42.57%) from female patients (Table.1). Isolation rate was highest in the age group 20-40 years followed by those above 60 years of age (Table 2).

Table 3 showing that Most of the isolates obtained were multi-drug resistant. Highest sensitivity was seen in Amikacin and Imipenem.

Graph 1: showing resistance patterns of *Pseudomonas aeruginosa*

**Discussion**

*Pseudomonas aeruginosa* is worldwide one of the most frequently isolated nosocomial gram negative bacteria from clinical specimens of hospitalized patients. Not only there has been an increase in the incidence of infections with this bacteria during the past decade but also a trend towards greater antibiotic resistance is seen. This could probably be due to an increase in the number of hospitalized or immune-compromised individuals. *Pseudomonas aeruginosa* is
intrinsically resistant to several antibiotics because of the low permeability of its outer-membrane to the antibiotics and also the constitutive expression of various efflux pumps, and beside this they also produce antibiotic-inactivating enzymes (e.g., cephalosporinases).  

The study showed that more than 50% of isolates of *Pseudomonas aeruginosa* were cephalosporin resistant. Resistant to fluoroquinolones was also high which is in concordance with a study by Parajuli *et al* which showed almost 92% of *Pseudomonas* spp. were cephalosporin resistant and even higher resistant to fluoroquinolones (95.8%). However sensitivity to Imipenem was comparatively high (65.3%). These findings were in agreement with those published by AL Kassi et al. They isolated different types of bacteria from burn’s patient and other units of hospital in Baghdad, which had shown that 86% of *Pseudomonas aeruginosa* isolates were sensitive to Imipenem and which was higher than the results obtained in our study. The results of our study also matched with the study by AL-Kadhmi *et al*, which showed good sensitivity of the isolates of *Pseudomonas aeruginosa* to Ciprofloxacin (61.1%) and high sensitivity to Imipenem which reached to (77.8%).

**Conclusion**

In conclusion, *Pseudomonas aeruginosa* which is a common Gram negative bacteria isolated from wound infections and also highly resistant to different types of antibiotics could be a reason for high morbidity and mortality in hospitalised patients. Therefore a regular surveillance of antibiotic resistance of these organisms is needed to prevent indiscriminate use of antibiotics leading to emergence of drug resistance among these pathogens.

**Limitations**

We were not able to evaluate the risk factors and the outcomes of nosocomial infections caused by this nosocomial pathogen because of unavailability of sufficient data from the patients whose infections were not of nosocomial origin.
